FreeCell Testbench Results

Problem 2:

Block Diagram at SSP level

Shows implementation of Tx FIFO, Rx FIFO, and Transmit/Receive Logic blocks with appropriate I/O connections.

Block Diagram at TransRec level

Shows implementation of TransmitLogic and ReceiveLogic. With appropriate connections, these blocks function as the larger TransRec Logic block.

[illegible]

Each module has its own tb for verification and targeted troubleshooting.

Both the Rx and Tx FIFOs use a 4-byte memory array to store data values. In order to indicate which location in mem to store new data or read existing data, we have write and read pointers. TxFIFO write pointer is incremented when transmit path is active (pwrite = 1), TxFIFO is *not* full and new data must be written. TxFIFO read pointer is incremented based on the transrec logic output inc_ptr, which is set high for one clock cycle when a local counter indicates that the data has been fully serialized. RxFIFO write pointer is incremented when read path is active (pwrite = 0), RxFIFO is *not* full and newly parallelized data must be written from SSP port. RxFIFO read pointer is incremented on positive edge of psel and pclk when read path is active (pwrite = 0). In order to set the full and empty flags, an additional pointer bit is used. This 'phase' bit tracks what cycle through the FIFO the pointer is on. When the read and write phases are the same *and* the pointer locations are the same, we can set a flag (empty for TxFIFO or full for RxFIFO), which then triggers the interrupt signal.
